Detroit Wastewater Treatment Plant discharges great amounts of organochlorines to Detroit River. The presence of organochlorines in water has remained at dramatically high levels for quite many years in Detroit River. Organochlorines pose a real danger. Those who eat contaminated fish - especially subsistence population, women of childbearing age, and children - are at risk. Organochlorines are potent neurotoxins and at very low levels can cause subtle but permanent damage to the brain and to the central nervous system. They are also carcinogenic to humans and wildlife.
